

DATE: January 26, 2024  
SUBJECT: Biomedical Research and Development Price Index: Fiscal Year 2023 Update and Projections for FY 2024–FY 2029

### **Summary**

- The estimated preliminary growth rate for the Biomedical Research and Development Price Index (BRDPI) in fiscal year (FY) 2023 is 3.9 percent, which is 0.2-percentage points lower than the 4.1 percent rate previously projected for that year.
- The actual growth rate for FY 2022 BRDPI is 4.6 percent, which is 0.1-percentage points higher than the 4.5 percent preliminary growth rate estimated last year.
- The BRDPI is projected to grow at the rate of 3.3 percent in FY 2024, 2.7 percent in FY 2025, and 2.6 percent between FY 2026 and FY 2029.
- The projected 3.2 percent growth rate of the Gross Domestic Product (GDP) price index for FY 2024 is 0.5-percentage points higher than the general rate of inflation as indicated by the U.S. Office of Management & Budget (OMB) annual projection of the GDP price index for FY 2024. It should be noted that the OMB's annual projection is from early December 2023, which did not account for revised data released by the Bureau of Economic Analysis (BEA), the Department of Commerce, towards the end of December 2023.
- The rate of growth of the BRDPI between FY 2012 and FY 2021 remained relatively low compared to its historical trend partially because of the past freeze on Federal civilian employee salaries and the cap on the compensation of extramural investigators. However, the growth rate of the BRDPI has remained above that of the GDP price index except for a few brief periods such as during the Oil Shocks of the 1970s and in 2012 when the federal salary cap dropped by 10 percent. The pandemic shock in the past few years with attendant supply chain disruptions contributed to a high general inflation rate. Additionally, the Russia-Ukraine war, since FY 2022, impacted raw material supplies, e.g., food exports from Ukraine and energy supplies controlled by Russia, with the latter factor playing a major role in raising underlying transportation costs due to higher fuel prices. These factors led to an uptick in both the growth rate of the BRDPI as well as the GDP price index, more so to the latter. Higher fuel costs rippled across various sectors of goods and services whose price movements are measured by the BRDPI and GDP price index, but items and their weighting vary in each index's basket. These factors indicated why the GDP price index growth rate exceeded the BRDPI growth rate in FY 2021 and FY 2022, and preliminary estimate for this index showed it remained so in FY 2023, but the difference is much smaller than it was in FY 2022. With the end of the pandemic, rising petroleum production (reducing gas prices), slow down of housing market prices growth rate after mortgage rates surged in 2023, and decline in prices of some goods there is a 2.4-percentage points drop in GDP price index in FY 2023 from FY 2022 reducing the gap between the BRDPI and GDP price index growth rates. In FY 2024 and thereafter, the estimated annual BRDPI growth rates are projected to exceed corresponding GDP price index as seen prior to the pandemic.
- The GDP price index measures not only the price change for consumer goods and services, but also the price change for goods and services purchased by businesses, governments, and foreign entities. The BRDPI measures changes in the prices of personnel services, supplies, and equipment purchased with NIH-issued awards to support biomedical research. More than 80 percent of the National Institutes of Health (NIH) annual budget expenditure typically goes towards funding extramural institutions, of which approximately 70 percent is received by academic institutions and 30 percent is distributed to non-academic institutions, which goes into the computation of the BRDPI. There are

many NIH expenditure categories, but the BRDPI is predominantly determined by the salaries of employees and consultants, and by factors that are primarily mark-ups of these salaries, i.e., fringe benefits and academic indirect costs. The academic salaries and wages increased by 4.0 percent in FY 2023 compared to 3.8% in FY 2022, only a 0.2 percentage points increase. The academic indirect costs increased by 3.9 percent, a 0.5 percentage point decrease from the rise experienced in FY 2022. The percentage change in non-academic salaries and wages remained almost unchanged. The rate of change of prices indexes of the BRDPI components unrelated to personnel costs, for example, inside-NIH utilities expenditure on fuel, electricity, gas, facility maintenance and repair, and travel-related costs, decreased significantly or increased at a rate lower than that in FY 2022, mostly due to the end of the pandemic. As a result, the overall prices measured within the BRDPI in FY 2023 changed at a rate lower than that in FY 2022 (3.9 percent versus 4.6 percent). The GDP price index growth rate also dropped in FY 2023 from its FY 2022 rate (4.6 percent versus 7.0 percent). With the effect of economic disruptions due to the pandemic dwindling away, the rise in the general inflation rate is expected to stabilize soon. We project that the growth of the BRDPI will continue to track the general rate of inflation measured by the GDP price index as we have seen historically.

### **Definition of the BRDPI**

The BRDPI measures changes in the weighted average of the prices of all the inputs (e.g., personnel services, various supplies, and equipment) purchased with the NIH budget to support research. The weights used to construct the index reflect the actual pattern, or proportions, of total NIH expenditures on each of the types of inputs purchased. Theoretically, the annual change in the BRDPI indicates how much NIH expenditures would need to increase, without regard to efficiency gains or changes in government priorities, to maintain NIH-funded research activity at the previous year's level.

### **Background and Updates to the Methodology Used to Estimate the BRDPI**

Appendix 3 below consists of four sections that provide a brief history of the BRDPI including reasons for changes in the methodology used to estimate and project future values of this price index. Appendix 3A briefly summarizes the role of the Bureau of Economic Analysis (BEA), the Department of Commerce and the NIH in the estimation process. Appendix 3B describes the benefits of the Fisher chain-weighted methodology that has been used to estimate the BRDPI since FY 2005.

Beginning with the BRDPI estimate for FY 2011, developed in December 2011, NIH has explicitly adjusted the estimates for changes in federal policy regarding the cap on salaries of investigators on extramural awards. See Appendix 3C for the history and details of this adjustment.

Since FY 2012 the salary cap has been linked to Federal Executive Level II salaries and that cap value has increased slightly each year. As a result, the cap on extramural salaries still constrains the growth of the BRDPI. Since FY 2012 the impact of the cap on BRDPI is markedly less than when it was frozen for FY 2011 or when it was reduced for FY 2012. However, the effect of the salary cap on the estimated growth of the BRDPI could increase over time. Consequently, we expect to continue to adjust the BRDPI for the effects of the salary cap. The reasons for and implications of the ongoing adjustment for the salary cap for the projection of future values of the BRDPI are summarized in Appendix 3D.

### **The FY 2023 Preliminary Estimate of BRDPI Growth and Data Revisions**

For FY 2023, the preliminary estimated growth rate of the BRDPI is 3.9 percent.<sup>1</sup> This estimate is 0.2 percentage points lower than the 4.1 percent BRDPI growth that was projected for FY 2023 in February 2023.

---

<sup>1</sup> The estimate for the most recent fiscal year (e.g., FY 2023) was provided by BEA in January 2024 in which BEA also provided a revised estimate for the prior fiscal years 2020, 2021, and 2022.

The actual estimated growth of the BRDPI for FY 2022 is 4.6 percent, which is 0.1-percentage points higher than previous year’s preliminary estimated value of 4.5 percent.

### **Projections for FY 2024–2029**

The BRDPI provides the best indicator of inflation (or deflation) conditions that NIH budgeted activities will experience in the future based on historical experiences for any completed fiscal year. The development of future NIH budgets benefits from consideration of how prices of the goods and services NIH expects to purchase in future years might change. We project the rate of change of the BRDPI for future years, but it would be unrealistic to assume that BRDPI will grow at the FY2023 rate or any fixed rate when general economic activity and the average growth of prices are expected to change from year to year. Though the pandemic ended, the Russia-Ukraine war is still ongoing making such projections volatile. Adjustment of future year projections to account for any anticipated changes in Federal policy is always desirable. Changes in Federal policy, as well as annual budget resources appropriated, can potentially influence the prices the NIH pays for goods and services used to support research and development (R&D).

The current projection methodology used for estimation of future annual changes in the BRDPI involves some sophisticated concepts but still reflects a straightforward approach that embodies three considerations. The first is the expected general rate of inflation of prices for the U.S. economy. The second is planned or expected changes in the cap on salaries of investigators on extramural awards. The third is the expected relationship between changes in the BRDPI and the general rate of inflation and changes in the salary cap.

For projections of the general rate of inflation the NIH relies on the projections prepared by the OMB and the quarterly GDP price indexes released by the BEA. We used the most recently issued OMB economic assumptions dataset (released in early December 2023) and BEA’s quarterly GDP price indexes from Table 1.1.4 released on December 21, 2023, as the source of future year percentage change rates for the GDP price index. The projected growth rate of the GDP price index in FY 2024 is 3.2 percent, 2.5 percent in FY 2025, 2.2 percent in FY 2026, and 2.1 percent between FY 2027 and 2029. The OMB’s forecast of the same is 2.7 percent in FY 2024, 2.2 percent in FY 2025 and 2.1 percent during the FYs 2026 to 2029<sup>2</sup>.

The salary cap increased 4.1 percent in 2023 and is scheduled to increase by 4.6 percent in 2024 according to the executive order that was signed by the President on December 21, 2023. Between FY 2025 to FY 2029, we assume that the salary cap will grow at 2.5 percent per year, which is its average rate of growth from FY 2018 to FY 2024.

The historical relationship between the BRDPI, the GDP price index, and the salary cap is summarized by a statistically estimated linear equation (by ordinary least squares regression) that relates the annual percent change in the BRDPI to the annual percent changes in the GDP price index and the salary cap. Using the data for the most recent eleven years<sup>3</sup> (FY 2013 through FY 2023) the estimated equation is:

$$\begin{aligned} & \text{(Projected percent change in the BRDPI)} \\ & = 1.4 + 0.41 \times (\text{percent change in GDP price index}) + 0.1 \times (\text{percent change in salary cap}). \end{aligned}$$

---

<sup>2</sup> GDP factors incorporated in calculations of rates for FY 2024 and later reflect economic assumptions issued by OMB in early December 2023 for budget formulation purposes during the time the BRDPI update was prepared (December 2023-January 2024). GDP price index values would not account for any revised economic assumptions that will be released later in 2024 by the OMB.

<sup>3</sup> We included data from the most recent eleven FYs.

Assuming the historical relationship will persist into the future, we plug the projected values of the GDP price index and the salary cap into the equation and derive the projected growth of the BRDPI for FY 2024 through FY 2029.

For FY 2023, after adjusting for the salary cap, the preliminary estimated growth of the BRDPI of 3.9 percent which is based on the 4.6 percent growth of the GDP price index and the 4.1 percent growth of the salary cap for FY 2023.

The projected 3.3 percent BRDPI growth for FY 2024 reflects the 3.2 percent growth in the GDP price index and the 4.6 percent increase in the salary cap. Based on the information that is currently available, NIH expects that after FY 2024 the BRDPI will increase approximately at the rate of 2.7 percent in FY 2025, and 2.6 percent per year from FY 2026 to FY 2029.

Forecasting the future path of price changes is an inherently imprecise exercise. We cannot expect OMB projections of future year GDP price index rates or NIH projections of future changes in the salary cap to be realized precisely each year. Likewise, the complex relationship between the general rate of inflation, the salary cap, and the BRDPI can change from year to year. However, NIH rigorously strives for an unbiased process—i.e., the projections miss high roughly as frequently as they miss low.

### **Summary Tables**

In Appendix 1, Table A depicts values of the percent change in the GDP price index and the BRDPI for the past ten years. Table B includes projected values of the BRDPI and the GDP Price Index for FY 2024 through FY 2029.

For the convenience of the reader, Table C illustrates how to translate *annual changes* into *annual levels* of the BRDPI. After designating a reference year, for which the value of the BRDPI is specified as 100, projections of the *annual levels* of the BRDPI are constructed using the following recursive relationship:

$$\text{BRDPI (for year } t) = \text{BRDPI (for year } t-1) \times [1 + \{\text{Percent Change (for year } t)\}]$$

In Table C, the calculations are presented for FY 1989 through FY 1992 using FY 1989 as the reference year (1989 = 100). To calculate the value for FY 1991, for example, the formula would be:  $110.5 = 105.4 \times 1.048$ . In other words, to derive the BRDPI value for FY 1991 (110.5), start with the FY 1990 BRDPI value (105.4) and multiply by one plus the annual change for FY 1991 ( $1 + [4.8/100] = 1.048$ ).

## **Appendix 3: Background and Modification of the Methodology Used to Estimate the BRDPI**

### **Appendix 3A. Background on the BRDPI Estimation Process**

In the early 1980s, the Bureau of Economic Analysis (BEA) in the U.S. Department of Commerce developed the Biomedical Research and Development Price Index (BRDPI). Under an interagency agreement with the NIH, each December the BEA provides an estimate of the BRDPI for the most recently completed fiscal year. In December 2023, for example, BEA transmitted an estimate for FY 2023. This estimate is referred to as “preliminary” because the initial data on prices available to the BEA in December are typically revised during the following year. Consequently, each December the BEA also provides a revised estimate for the prior fiscal year, i.e., the estimate for FY 2022 was revised in December 2023.

The Office of the Director at NIH projects future year values based on a methodology described below. An updated table of BRDPI annual estimates and future-year projections is posted on the NIH website each year shortly after the release of the President’s Budget, typically in early February. Refer to the following link <http://officeofbudget.od.nih.gov/gbiPriceIndexes.html>, or use the search engine at <http://www.nih.gov/> to find “BRDPI.”

### **Appendix 3B. Use of the Fisher Chain-Weighted Index Methodology to Estimate the BRDPI**

This section is included for users interested in more of the technical details regarding methods used to estimate annual values of the BRDPI.

As stated in the memo above, the weights used to construct the BRDPI reflect the actual pattern (or the proportions) of total NIH expenditures spent on each of the types of inputs purchased with the NIH budget (e.g., personnel services, various supplies, and equipment). In fact, the use of weights specific to the NIH budget is what distinguishes the BRDPI from other price indexes designed to reflect different patterns of expenditures.

Prior to 2006, the BEA estimated the BRDPI using a fixed weight (or Laspeyres) index. This type of index compares prices over several years using a fixed set of weights based on the composition of expenditures in a single, specified base year (say 1993 or 2003).

Beginning with the revised estimate for FY 2005 (published in December 2006) the BEA now estimates the BRDPI using a Fisher chain-weighted index methodology. The chain-weighted methodology improves the accuracy of the BRDPI and is consistent with the methodology BEA adopted in 1996 to estimate the gross domestic product and its component series. For the interested reader, the BEA’s *Concepts and Methods of the U.S. National Income and Product Accounts* as well as five articles in BEA’s publication, *Survey of Current Business*, discuss the reasons BEA now uses the chain-weighted methodology (see Appendix 2 above).

In less technical terms, chain weighting means that the expenditure weights used to estimate the BRDPI are updated each year. Also, when estimating the growth of the BRDPI between two consecutive years (say 2005 and 2006) the Fisher Price Index reflects the average experience of two slightly different

indexes: the first index uses first year weights (e.g., 2005) to estimate average growth in prices; the second index uses second year weights (e.g., 2006). To estimate growth over several years, the consecutive year indexes are multiplied together, or chained. (As an analogy, think of calculating compound growth on your retirement portfolio over ten years as the mix of stocks and bonds changes from year to year.)

By contrast to the chain weighting methodology, the previously used fixed-weight (or Laspeyres) index approach can result in a “substitution bias” that tends to overstate price increases for periods after the base year and understate price increases for periods before the base year. This bias occurs because use of the fixed-weight index implicitly assumes the composition of the items being priced does not change over time. In fact, the mix of items purchased and included in a price index tends to shift over the years. The shift in purchases may be a response to changes in relative prices or to advances in technology which provide new opportunities and new tools for investigation (e.g., more computers and automated test equipment and fewer laboratory assistants). Or the mix may reflect changes in policy with a larger share of the NIH budget allocated to support of extramural research and less to inside NIH activities, including intramural research and administration of extramural research.

During periods close to the base year, differences in the composition are usually small, and a fixed-weight index provides a good approximation. Farther away from the base period, however, larger differences in expenditure composition are likely. Consequently, weighting formulas that allow for changes in composition each year provide a better measure of both year-to-year price changes and long-term trends.

In response to BEA recommendations, in past years the expenditure weights used to estimate the BRDPI were occasionally updated, or rebased, to reduce the problem of substitution bias. In the BRDPI Table of Annual Values listed on the NIH website and in the attached Table A, the values of the BRDPI for FY 1999-2004 are constructed using the FY 2003 expenditure weights; the FY 1991-1998 values are based on FY 1993 weights; the FY 1986-1990 values are based on FY 1988 weights; and the FY 1979-1985 values are based on FY 1984 weights. The pre-1979 values of the BRDPI were estimated using a preliminary methodology with a less detailed set of expenditure weights. Pre-1979 values are not likely to be as accurate as the later year values because of the less precise methodology.

### **Appendix 3C. Adjusting the BRDPI for the Cap on Extramural Compensation**

Every year since 1990, Congress has legislatively mandated a provision limiting the direct salary that an individual may receive under an NIH grant.<sup>4</sup> The cap has been increased most years at a moderate rate. Although the increase is generally somewhat below the average growth in academic salaries, in years before FY 2011 the impact of the salary cap on the estimated growth of the BRDPI was negligible. However, for FY 2011 the NIH salary cap was frozen at the previous year’s level. The cap “freeze” had a noticeable effect on the estimated change of the BRDPI for FY 2011.

The limitation on the direct salary that an investigator may receive under an NIH award might not reduce the investigator’s effective income. The host institution or another funding source may make up the difference. However, changes in the cap affect what NIH pays for an investigator’s research effort if the investigator’s annual compensation rate exceeds that cap. Given the definition of the BRDPI as an input

---

<sup>4</sup> [http://grants.nih.gov/grants/policy/salcap\\_summary.htm](http://grants.nih.gov/grants/policy/salcap_summary.htm) and <http://grants.nih.gov/grants/guide/notice-files/NOT-OD-11-073.html>

price index for the NIH budget, the effect of the cap on the price NIH pays for an investigator's effort must be considered.

For FY 2012, the level of the cap dropped from \$199,700 to \$179,700. The reduction in the cap on investigator salaries, flat civilian Federal salary levels, and limits on the growth of fellowship and training stipends and related expenses on training awards combined to reduce the estimated BRDPI growth for FY 2012 and the projected growth for subsequent years.

For FY 2012 NIH estimated the share of academic salaries subject to each of the two salary caps. Using a sample of successful applications for competing new and renewal NIH awards the NIH extracted data on salaries from the detailed budget requests submitted as part of each application. Our best estimate for NIH awards to academic institutions:

- 12.9% of requested salaries are subject to the original cap of \$199,700.
- 14.4% of requested salaries are subject to the lower cap of \$179,700.
- -10.7% is the average reduction due to lowering the cap (from \$199,700 to \$179,700) for the 14.4% of salaries subject to the lower cap.<sup>5</sup>

## **Appendix D. Unadjusted and Adjusted Values of the BRDPI**

Since FY 2012 the salary cap has been linked to Federal Executive Level II salaries and that cap value has increased slightly each year. As a result, the cap on extramural salaries still constrains the growth of the BRDPI. The impact of the cap is markedly less than when it was frozen for FY 2011 or when it was reduced for FY 2012.

---

<sup>5</sup> Information on base salaries and requested salaries for each member of the proposed research staff can be found in the detailed budget tables included as part of the project proposal. The salary information must be extracted from a sample of PDF file copies of applications and placed in Excel files for analysis.

The sample of project budgets was stratified by types of awards (e.g., "R01, R21, P01), whether the award was made to a medical school or to a non-medical component of a university, and whether the degree of the corresponding principal investigator (PI) was an MD (including dual MD and PhD degrees) or something else (primarily a PhD).

The results for each cell in the three-dimensional sampling strata were then aggregated to estimate the overall share of requested salaries subject to each cap. The relative weight for each combination of type of award, medical/nonmedical component, type of degree was based on the distribution of all award amounts to academic institutions for FY 2011.

BEA estimated the growth in academic salaries for the BRDPI at 2.82 percent for FY 2011 and 3.24 percent for FY 2012. These estimates were based on the AAMC survey of salaries of medical school faculty and the AAUP survey of university salaries. Adjusting for the freeze on the salary cap for FY 2011 and the reduction of the salary cap for FY 2012, the estimated growth in academic salaries was reduced to 2.46 percent and 1.23 percent respectively.

At the request of the NIH, the BEA re-estimated the BRDPI using the rates of growth of academic salary rates adjusted for the cap freeze and the cap reduction. The revised estimates of BRDPI growth captured the direct effects of reduced growth in academic salaries on the growth of the overall BRDPI. It also captured the indirect effects of academic salary growth through its effects on growth of fringe benefit rates, academic indirect costs and estimates of growth of compensation for consultants and for personnel on awards to non-academic institutions.

At one point we thought the need to adjust the BRDPI estimates for the effect of the salary cap would be temporary. We now believe it is important to adjust for the effects of the salary cap if it is in existence, even if the effect is small in some years. The salary cap is likely to remain in place indefinitely. It tends to be tied to the growth of compensation for federal civilian salaries. In recent years, civilian salaries have on average grown less each year than the growth in academic salaries. If average academic salaries continue to grow faster than the cap on salaries of extramural investigators, the impact of the cap on the estimated BRDPI will increase over time.

Since FY 2011 the estimates of the BRDPI that NIH has posted have included adjustments for the effects of the salary cap. To calculate the adjusted series, NIH begins with a preliminary series of BRDPI estimates unadjusted for the salary cap. To avoid confusion, this preliminary series is not routinely published or posted.

BEA prepares estimates of the unadjusted BRDPI growth series using the traditional methodology using extramural employee compensation data that are not limited by the salary cap. NIH then calculates the effective growth of academic salaries as the result of the salary cap<sup>6</sup> and asks BEA to re-estimate BRDPI growth subject to the slower growth in extramural compensation. The effect of this adjustment for the FY 2022 value was to reduce the estimated growth of the BRDPI by 0.2 percentage points, from 4.8 percent, unadjusted, to 4.6 percent growth after adjusting for the effect of the salary cap.

Since 2021, the projections for GDP price index percentage changes were estimated using OMB economic assumptions released in December, included in the ‘ALT\_PRICE’ tab of the excel file provided by the OMB.

For 2023 BRDPI estimation, NIH used the adjusted BRDPI series for the projection methodology described in the cover memo above because it produces a more adequate statistical fit than the unadjusted BRDPI series. This projection methodology accounts for changes in both the GDP price index and the salary cap in their impact on the BRDPI, whereas the old methodology focused just on the GDP price index (though the resulting projections could be adjusted for projected changes in the salary cap). By accounting for both variables, the new equation better captures the effects of the major factors contributing to the cost of NIH research.

---

<sup>6</sup> Effectively, this is a weighted average. The percentage of extramural salaries subject to the cap grows at the same rate as the salary cap. The salaries not subject to the cap grow at the constrained rate.
